

A weather balloon rising through the atmosphere, has its volume expanding from  $6.0 \text{ m}^3$  to  $15 \text{ m}^3$  as the temperature drops from  $22^\circ\text{C}$  to  $-12^\circ\text{C}$ . If the initial gas pressure inside the balloon is  $1.0 \text{ atm}$ , what is the final pressure?

Given:

Initial volume of the balloon:  $V_i = 6.0 \text{ m}^3$

Final volume of the balloon:  $V_f = 15 \text{ m}^3$

Initial temperature in the balloon:  $T_i = 22^\circ\text{C} = 295 \text{ K}$

Final temperature in the balloon:  $T_f = -12^\circ\text{C} = 261 \text{ K}$

Initial gas pressure in the balloon:  $P_i = 1.0 \text{ atm}$

To determine: final gas pressure in the balloon:  $P_f$

Use formula:

$$PV = nRT \text{ -----(1)}$$

**R is the gas constant and has a value of  $8.314 \text{ J / mol}$**

Then:

$$P_i V_i = nRT_i \text{ -----(2)}$$

$$P_f V_f = nRT_f \text{ -----(3)}$$

Combining (2) & (3) and rearranging:

$$P_f = P_i V_i T_f / V_f T_i \text{ -----(4)}$$

Substituting  $P_i$ ,  $V_i$ ,  $T_i$ ,  $T_f$  and  $V_f$  in (4):

$$P_f = (1.0 \times 6 \times 261) / (15 \times 295) = 0.35 \text{ atm}$$
